Lab 1

1. Getting Start

1.1. Install Python

You can download and install the latest version of Python [here](#).

1.2. Install IDE

The two most popular IDEs for running Python are PyCharm, VSCode.

1.3. Create and run your first program

To get started with PyCharm, please follow the instructions provided [here](#).

To get started with VScode, please follow the instructions provided [here](#)

2. Exercises

2.1. Exercise 1

Assign variable x with 15, and variable y with 30. Find their sum and assign the result to a variable z. Then print the variable z.

Hint: `print(x)` will print the value of x to the console.

2.2. Exercise 2

We have a variable named x which is assigned a floating point number, and a variable y which is assigned with an integer. We find the sum of these two numbers, and store the result in variable z. Then we print the data type of variable z using `type()` built-in function. What would be the type of z?

Hint: if x is an integer, `type(x)` will return the type of x, which is integer.

2.3. Exercise 3

Write a program to multiply four pre-defined numbers and assign the result to a variable. Then, print both the value stored in the variable and its data type.
